| <p>Global atmospheric circulation and heat transfer</p> | <p>The atmosphere operates as a global system transferring heat and energy</p> | <p><i>The features of the global atmospheric circulation</i></p> | <p>Wind is caused by differences in atmospheric pressure – air moves from high pressure to low pressure – the greater the difference in pressure, the stronger the winds. Towards the poles, the Sun's energy spreads over a large area, resulting in low temperatures and high pressure. At the equator, the Sun's energy is concentrated over a small area, resulting in high temperatures and low pressure. The difference in air pressure on the Earth's surface causes global patterns of air circulation (cells) from areas of high pressure to areas of low pressure. The Tri-cellular model 1) Warm air rises from the equator, creating a belt of low pressure. As the air rises, it cools. 2) The resulting condensation creates clouds and rain that move north and south of the equator. 3) The ITCZ (Inter-tropical convergence zone) is a band of low pressure around the Earth which generally lies near to the equator. The trade winds of the northern and southern hemispheres come together here, which leads to the development of frequent thunderstorms and heavy rain. 4) At 30° north and south of the equator, the cold, dry air sinks, creating high pressure and clear skies (Hadley Cell). 5) When the sinking air reaches the Earth's surface, it moves either back to the equator or towards the poles. 6) At 60° north and south of the equator, the surface air meets colder air from the poles, which causes it to rise, creating a belt of low pressure (Ferrel Cell). 7) The air rises and cools. At a high level, this moves either back to the equator or towards the poles. 8) At the poles, the cool air sinks to the Earth's surface, creating high pressure. The air then moves back towards the Equator (Polar Cell).</p> | <p>Air Atmosphere Wind Air pressure Global Circulation Angle of incidence Tr-Cellular model Equator Inter-Tropical Convergence Zone (ITCZ) hemisphere Latitude Longitude Hadley cell Ferrel Cell Polar cell</p> | <p>Use and interpretation of line graphs/bar charts showing climate change</p> |  |
| | | <p><i>How circulation cells and ocean currents transfer and redistribute heat energy across the Earth.</i></p> | <p>Ocean currents are large scale movements of water that transfer heat energy from warmer to cooler regions. Surface currents are caused by winds and help transfer heat away from the equator. The Gulf Stream is an example of surface ocean movements from the Caribbean to the UK. Deep ocean currents, known as Global Thermohaline Circulation, also transfer heat from the equator to the poles but are driven by differences in water density. When water freezes at the poles, the surrounding water gets saltier, increasing its density. As it gets denser it sinks, causing warmer water to in at the surface – creating a current. This warmer water is cooled and sinks, continuing the cycle. The Humboldt Current brings cold water back from the poles to the equator, where it is heated.</p> | <p>Ocean currents Surface currents Gulf Stream Global Thermohaline Circulation Humboldt current Density Salt</p> | | |
| | <p><i>How climate has changed in the past over different time scales: glacial and interglacial periods during the Quaternary period.</i></p> | <p>The average climatic conditions of the Earth change naturally over time, creating both warmer and colder periods. The Quaternary Period is the most recent geological time period from 2.6 million years ago to the present day and includes the whole of human history. Before the Quaternary, global temperatures were warmer and quite stable. During the Quaternary global temperatures have shifted between cold glacial periods that last for around 100,000 years, and warmer interglacial periods that last for around 10 000 years.</p> | <p>Climate Geological time Quaternary Glacial Interglacial</p> |  | | |

| | <p>The global climate was different in the past and continues to change due to natural causes</p> | <p><i>Causes (Milankovitch cycles, solar variation, volcanism) and evidence (ice cores, pollen records, tree rings, historical sources) for natural climate change.</i></p> | <p>These variations were caused by natural events:</p> <p>Milankovitch Cycles</p> <ul style="list-style-type: none"> - Earth's orbit changes approx. every 100 000 years from a circular orbit (warmer) to a more elliptical orbit (colder) (Eccentricity) - Roughly every 40 000 years the Earth's tilt varies = greater angle of tilt = hotter summers and colder winters (Axial tilt) - The Earth 'wobbles' on its axis roughly every 24 000 years resulting in differences between seasons. (Precession) <p>Solar variation</p> <p>Lower solar radiation output levels result in glacial periods, higher solar radiation output levels result in interglacial periods.</p> <p>Tectonic activity</p> <p>Large-scale volcanic eruptions can eject ash and dust into the atmosphere blocking out solar radiation causing temperatures to fall</p> <p>Evidence</p> <p>Historical sources such as diaries and painting</p> <p>Ice Cores trap volcanic bubbles, revealing information on climate when the ice is formed</p> <p>Tree rings show climate conditions by the size of their growth – thick rings mean warm, wet conditions</p> <p>Pollen records provides evidence on warm and cold growing conditions</p> | <p>Variations Natural Causes Milankovitch Cycles Eccentricity Axial tilt Precession Circular orbit Elliptical orbit Seasons Solar radiation Tectonic Volcanic eruptions Evidence Historical sources Ice cores Tree rings Pollen</p> | <p>Use and interpretation of line graphs/bar charts showing climate change</p> |  |
| <p>Global atmospheric circulation and heat transfer</p> | <p>Global climate is now changing as a result of human activity</p> | <p><i>How human activities (industry, transport, energy, farming) produce greenhouse gases (carbon dioxide, methane) that cause the enhanced greenhouse effect.</i></p> <p><i>Negative effects that climate change is having on the environment and people (changing patterns of crop yield, rising sea levels and retreating glaciers).</i></p> | <p>The Greenhouse Effect – how the atmosphere keeps the Earth warm and sustains life on Earth. Heat energy (insolation) passes through the atmosphere and heats the Earth's surface and oceans. Heat is radiated back into space from the Earth. Greenhouse gases such as CO₂, H₂O, and CH₄ trap some of the heat in the Earth's atmosphere.</p> <p>Enhanced Greenhouse effect</p> <p>Human activities have increased the levels of greenhouse gases and therefore increased temperatures since the Industrial Revolution through:</p> <ul style="list-style-type: none"> - Industry – production of consumer goods using fossil fuel energy releases greenhouse gases. Cement made from limestone contains carbon which is released when cement is produced. Industrial waste releases methane through waste decay - Transport – most transport runs on fossil fuels. Increased car ownership increases greenhouse gas emissions. Residential and business properties rely on fossil fuels for electricity and heating - Agriculture including rice production and livestock produce lots of CH₄. Deforestation for agriculture reduces the amount of CO₂ trees absorb and store. <p>Negative effects Environment</p> <ul style="list-style-type: none"> - melting ice sheets, retreating glaciers = sea level rise = coastal flooding = contamination with salt causing plants to die. - Arctic melting could change the Gulf Stream bringing colder temperatures in Western Europe. <p>People</p> <ul style="list-style-type: none"> - Changes in climates near the equator e.g. The Sahel means longer periods of drought so lower crop yields. - Many low-lying islands like the Maldives face greater flood risk from rising sea levels. | <p>Greenhouse effect Insolation Atmosphere Radiated Enhanced Greenhouse effect Greenhouse gases Industrial Revolution Industry Consumer Fossil fuels Waste decay Transport Residential Agriculture Livestock Deforestation Glaciers Flooding Contamination Drought Crop yields Sea level</p> | |   |

| Tropical cyclones | Tropical cyclones are extreme weather events that develop under specific conditions and in certain locations | | <p>Tropical cyclones develop in a band of low pressure and warm temperatures between 5° and 30° north and south of the equator through global atmospheric circulation</p> <p>Sea temperature = 26°C or higher Water depth = 60-70m Low wind shear</p> <p>Warm, moist air rises, leading to condensation and low air pressure, increasing surface winds. Easterly trade winds move tropical storms to the west near the equator. Coriolis effect (Earth's rotation) makes storms spin. Energy increases over warmer water, loses strength over land. Majority of storms occur in northern hemisphere</p> <ol style="list-style-type: none"> 1) Warm, moist, unstable air above the ocean rises, creating an area of low pressure below 2) Surrounding cooler air is drawn into the area of low pressure, causing winds 3) The cool drawn-in air warms up and takes on moisture, causing it to rise 4) The large mass of rising, warm air cools and condenses, forming large cumulonimbus clouds and heavy rain 5) Latent heat released during condensation helps to power the storm 6) As more air is drawn in the area of low pressure, the Earth's rotation causes wind to spiral in the storm's centre, or eye (Coriolis effect) 7) Colder, drier air sinks in the eye of the storm, creating calm conditions. Prevailing winds then push the storm inland 8) The storm continues to get bigger and stronger until it reaches land or colder seas. Landfall and friction slow the storm down. <p>The centre is called the eye – descending air, low pressure light winds, no rain, high temperature</p> <p>Eye wall – spiralling rising air, very strong winds, storm clouds, torrential rain, low temperatures Edge – lower wind speed, smaller clouds, scattered rain, temperature increases</p> | Tropical cyclones Latitude Wind hear Moist Trade winds Coriolis effect Rotation Hemisphere Evaporation Condensation Precipitation Cumulonimbus clouds Spiral Vortex Landfall Friction Eye Eye wall Edge | Use of GIS to track the movement of tropical cyclones |  |
| Tropical cyclones | | Characteristics, frequency and geographical distribution of tropical cyclones and how these change over time | <p>Names and locations</p> <ul style="list-style-type: none"> - Hurricanes = Atlantic Ocean - Typhoons = Pacific Ocean - Cyclones = Indian Ocean <p>June – November = northern tropics November – April = southern tropics</p> <p>Circular in shape, hundreds of kilometres wide, lasting 7-14 days, spin anti-clockwise in the north and clockwise in the south</p> <p>Increased frequency and intensity due to the enhanced greenhouse as a result of increased greenhouse gases released into the atmosphere through human activities</p> | Hurricanes Typhoons Cyclones Clockwise Anti-clockwise Frequency Intensity | Use of GIS to track the movement of tropical cyclones | |
| | | Reasons why tropical cyclones are natural weather hazards (high winds, intense rainfall, storm surges, coastal flooding and landslides). | Measured using the Saffir-Simpson Scale – Cat 5 is the strongest High winds – up to 250 km/h Rainfall – trillions of litres of water per day Storm surges – rise in sea level through low pressure and high winds Coastal flooding - result of storm surges Landslides – rainfall makes hills unstable | Saffir-Simpson scale Storm surges | Use of weather and storm surge data to calculate Saffir-Simpson magnitude | |
